

C.5 Doppler effect

Wave behaviour · IB Diploma · Concept guide and original exam-style practice

Understand the concept

The Doppler effect is the change in observed frequency (or wavelength) of a wave due to relative motion between source and observer: frequency increases when source and observer approach each other and decreases when they recede. For sound waves (source moving, observer stationary, speed of sound v), the observed frequency is $f_{\text{obs}} = f_{\text{source}} \cdot v / (v \pm u_s)$, with the sign depending on whether the source approaches ($-$, giving higher f_{obs}) or recedes ($+$, lower f_{obs}); analogous expressions exist for a moving observer. For light, at speeds much less than c the fractional shift in wavelength/frequency approximates $\Delta f/f \approx \Delta \lambda/\lambda \approx v/c$, used in astronomy to measure the redshift (receding) or blueshift (approaching) of distant sources such as galaxies, revealing radial velocity.

Worked example: follow the reasoning

A police car siren emits sound at 600 Hz and moves towards a stationary observer at $30 \text{ m}\cdot\text{s}^{-1}$. Speed of sound in air is $340 \text{ m}\cdot\text{s}^{-1}$. Find the observed frequency.
 $f_{\text{obs}} = f_{\text{source}} \times v / (v - u_s) = 600 \times 340 / (340 - 30) = 600 \times 340 / 310 = 600 \times 1.097 = 658 \text{ Hz}$.
Answer: $f_{\text{obs}} \approx 658 \text{ Hz}$.

Quick check · multiple choice

A star's light is observed to have its spectral lines shifted to longer wavelengths (redshifted) compared to laboratory values. What does this indicate about the star's motion relative to Earth?

- A Moving towards Earth
- B Moving away from Earth
- C Stationary relative to Earth
- D Moving perpendicular to the line of sight only

Write your choice: _____

Structured practice

Answer in the space provided. Show working and units where relevant.

- 1 An ambulance travels at a constant speed towards a stationary observer, sounding its siren at a source frequency of 500 Hz. The observer hears a frequency of 560 Hz. Take the speed of sound in air as $340 \text{ m}\cdot\text{s}^{-1}$. [7]
- (a) State whether the ambulance is moving towards or away from the observer, with a reason.
- (b) Calculate the speed of the ambulance.
- (c) Calculate the frequency the observer would hear immediately after the ambulance passes and moves away at the same speed.

Final answer: _____

Answers and explanation

Question 1 [7]

(a) Towards the observer, because the observed frequency (560 Hz) is higher than the source frequency (500 Hz), consistent with an approaching source (compressed wavefronts).

(b) $f_{\text{obs}} = f_{\text{source}} \cdot v / (v - u_s) \rightarrow 560 = 500(340) / (340 - u_s) \rightarrow 340 - u_s = 500 \times 340 / 560 = 303.6$
 $\rightarrow u_s = 340 - 303.6 = 36.4 \text{ m} \cdot \text{s}^{-1}$.

(c) Receding: $f_{\text{obs}} = f_{\text{source}} \cdot v / (v + u_s) = 500(340) / (340 + 36.4) = 170000 / 376.4 = 451.6 \text{ Hz} \approx 452 \text{ Hz}$.

Quick check answer

B. A redshift (increased wavelength) indicates the source is receding from the observer, consistent with the Doppler effect for light.

Self-assessment

Compare each credited step with your own answer. Fix the first reasoning or content error, then retry the practice question without looking at the solution.
